

## **ABSTRACT**

Configuration settings are described which may be utilized to indicate a configuration of an application. In an exemplary implementation, a method includes validating a configuration setting of a first application for use with a second application. The configuration setting includes a first field and a first description of a first condition for the first field. The second application is composed of computer instructions that include an attribute. The attribute provides a second description of a second condition for a second field. If the first field corresponds to the second field, then the first description of the first condition is compared with the second description of the second condition to determine whether the first condition is met by the second condition. If the first condition is met, the configuration setting is determined to be valid for use with the second application.
